On the cross-sectional predictability of stock returns

This research has accumulated to a veritable "factor zoo"

- The number of these strategies raises concerns about data mining (Harvey, Liu, and Zhu (2016) and Chordia, Goyal, and Saretto (2020)).
- On the other hand, we can predict returns using past returns alone

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Fama-MacBeth monthly regression on lagged returns

$$r_{i,t} = \rho_0 + \sum_{j=1}^{12} \left(\rho_j \times r_{i,t-j} \right) + \epsilon_{i,t}$$

Momentum and Reversals

Momentum at 3-12 month horizons

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

reversals at monthly horizons

What causes momentum?

- Informed investors make rational decisions
- ► Uninformed investors are "quasi-rational" → underassess the quality of signals they do not themselves produce (Odean (1998) and Luo, Subrahmanyam, and Titman (2021)).
- Uninformed provide "too much liquidity" to their informed counterparts which causes momentum.

- Absorption by risk averse agents of noise trades unrelated to fundamentals.
- ▶ Noise trades temporarily move prices away from fundamentals.
- These deviations are corrected when noise trades are reversed and when information is revealed. These corrections generate reversals.

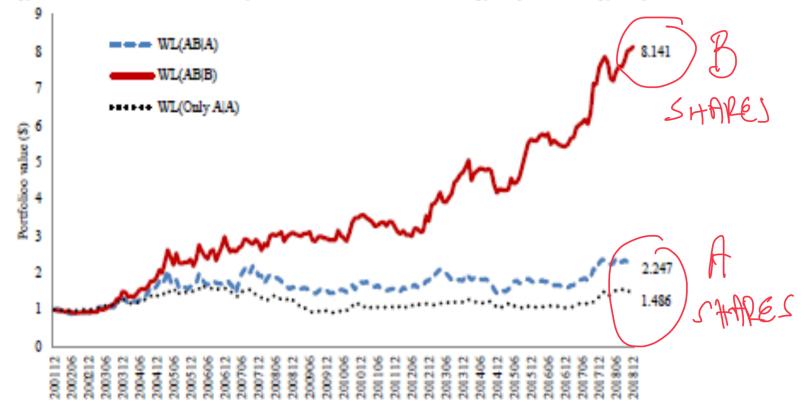

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Our setting (EARLIER PAPER WITH ANDY CHVE) • Different share classes on same firm

- In China, A and B shares \rightarrow different clienteles.
 - A mostly retail
 - Foreign institutions virtually absent in A but materially present in B
 - Domestic institutions not allowed in B

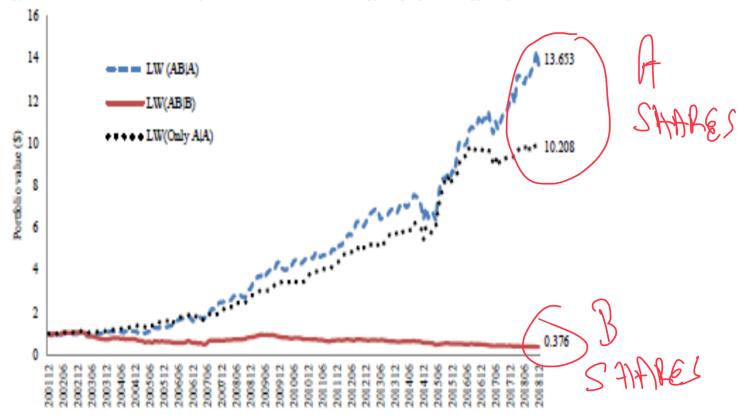

Momentum profits, plotted

Figure 3A Cumulative monthly returns to momentum strategies (value-weighted)

Monthly reversals, plotted

Figure 4B Cumulative monthly returns to reversal strategies (Equal-weighted)

The evidence so far

- A shares have more noise traders which means more reversals
- B shares are traded mostly by institutions which means more momentum arising from underreaction to fundamentals

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Goyal, Jegadeesh, and Subrahmanyam

Examine a number of explanations for momentum

・ロト・日本・モト・モー ショー ショー

find underreaction is the most likely cause

Our paper

- There is a "gradual" transition from reversals to momentum as lag length increases
- We provide a model that allows for this transition
- Model features:
 - Two types of risk-averse active investors and noise traders
 - Risk-averse investors underreact to information, and absorb noise trades at a premium
 - Noise trades have varying horizons
- Model yields new empirical implications, which receive support

The economic setting: Assets

Risky stock traded at Dates 0, 1, 2, and 3.

• Its liquidation value at Date 4 is θ , where $\theta \sim N(0, \nu_{\theta})$.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Supply of stock normalized to 0.

Risk-free asset; price and return are set to 1.

Investors

Unit mass of risk-averse active investors Each has standard exponential utility:

$$U(W_{i4}) = -\exp(-AW_{i4}),$$

where W_{i4} is the investor's final wealth.

- Noise traders
 - At each of Dates t (t = 1, 2, or 3), a new noise demand z_t is drawn from $N(0, \nu_{z_t})$.
 - $(1 \mu)z_t$ is unwound at Date t + 1; the rest of this demand, μz_t , is unwound at Date t + 2.
 - The net noise demand is z₁ (z₂ + µz₁) (z₃ + µz₂) at Date 1 (2) (3).

Information

Date 0: Starting date; no information

- Date 1: Public signal f = θ + ξ + ε + ζ; ξ (ε) (ζ) drawn from N(0, ν_ξ) (ν_ε) (ν_ζ); can be an analysts' forecast or managerial guidance
- Date 2: A second public signal F = θ + ξ + ε; can be an earnings announcement
- Date 3: Mass λ of "informed" active investors observe a private signal s = θ + ξ.

Beliefs

Uninformed investors underassess the informativeness of s.

- Suppose $\theta = \theta_1 + \theta_2$, where $\theta_1 (\theta_2)$ is mean-zero normal with variance $\nu_{\theta_1} = \kappa^{-1} \nu_{\theta} (\nu_{\theta_2} = (1 \kappa^{-1}) \nu_{\theta})$.
- Uninformed investors believe that s = θ₁ + ξ, so s reveals only the component θ₁.

Correspondingly, they believe f = θ₁ + ξ + ϵ + ζ and F = θ₁ + ξ + ϵ.

Intuition

Noise traders cause reversals

- Informed traders' underreaction to long-term fundamentals causes momentum
- ► Shorter noise trader horizons → short-term reversals; longer noise trader horizons implies reversals attenuate momentum
- Reversals are attenuated following information releases (due to underreaction)

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

 More noise trading implies stronger reversals and less momentum

Reversal and momentum measures

The short-term predictability measure:

$$\begin{split} \mathcal{S} &= \frac{1}{3} \bigg[\mathrm{Cov}(P_1 - P_0, P_2 - P_1) \\ &+ \mathrm{Cov}(P_2 - P_1, P_3 - P_2) + \mathrm{Cov}(P_3 - P_2, P_4 - P_3) \bigg], \end{split}$$

The long-term predictability measure:

$$\mathcal{L} = \operatorname{Cov}(P_2 - P_0, P_4 - P_2),$$

(ロ)、(型)、(E)、(E)、 E) の(()

Simple case with closed-form solution

- λ = 0; a converging case where the mass of uninformed relative to informed investors is large.
- Uninformed investors directly learn the signal s.
- ▶ The Date-3 noise trade $z_3 \equiv 0$, so that the Date-3 price fully reveals informed investors' private signal *s*.

- Further, we assume that $0 \le \mu \le 1$.
- [general case illustrated numerically]

The case without noise trades

That is, $z_t \equiv 0$ and $\nu_{z_t} = 0 \ \forall t$.

• The long-term serial covariance $\mathcal{L}^{K} > 0$.

All short-term autocovariances are also positive.

The case with noise trades

Noise trades arise at Dates 1 and 2 (i.e., $\nu_{z_1} = \nu_{z_2} = \nu_z > 0$). Let $\nu_z \in [U_1, U_2]$.

• If μ is sufficiently small, then long-run predictability $\mathcal{L} > 0$.

- Short-term predictability S < 0.
- As ν_z increases, for sufficiently small μ, L and S decrease
 (L becomes less positive).
 (S becomes more negative).

Skipping a period and momentum profits

▶ Define a parameter \mathcal{L}^*

$$\mathcal{L}^* \equiv \operatorname{Cov}(P_2 - P_0, P_4 - P_3),$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

We obtain the following result:

Skipping a period enhances the momentum effect, i.e., *L*^{*} > *L*.

Longer-lag return predictability

▶ Recall that S < 0

Define two parameters:

$$\begin{aligned} \mathcal{S}_{(2)} &= \frac{\operatorname{Cov}(P_1 - P_0, P_3 - P_2) + \operatorname{Cov}(P_2 - P_1, P_4 - P_3)}{2}, \\ \mathcal{S}_{(3)} &= \operatorname{Cov}(P_1 - P_0, P_4 - P_3). \end{aligned}$$

•
$$S_{(3)} > 0.$$

If μ > 0, then as ν_z increases from zero, S₍₂₎ is first positive and then turns negative.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Return predictability around earnings announcement dates

- Let Cov_E ≡ Cov(P₂ − P₁, P₃ − P₂) denote the covariance around the earnings announcement
- Provided that µ is sufficiently small, and F is not too imprecise, Cov_E > S (underreaction dominates reversals).

Empirical Implications

Markets transition from reversals to momentum

- reversals at short lags
- weak predictability at longer lags
- momentum at even longer lags.
- Momentum profits ↑ when we skip a month between formation and holding periods
- Reversals \$\geq\$ after earnings announcements
- ▶ \uparrow Momentum $\rightarrow \downarrow$ reversal profits (across countries and time)
- Countries with ↑ noise trading have ↑ reversals
- Short-term reversals
 when absolute order imbalance of retail investors

Culture and noise trading

- We consider two cultural attributes previously considered by others
 - Individualism (IDV Chui Titman, and Wei (CTW) (2010))
 - Uncertainty Avoidance i.e., desire to avoid long-run ambiguity (UAI - Nguyen and Truong (2013))
- ▶ \uparrow IDV \rightarrow \uparrow overconfidence and \uparrow momentum (as in CTW)
- ↑ UAI → ↓ focus on ambiguous long-run fundamentals → ↑
 noise trades and ↑ reversals (new)

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ● ●

$r_{i,t-1} imes \sigma(\textit{Retail OIB})_{i,t-1}$			(0.85) -0.0138 (-3.60)

Conclusions

- Markets transition from reversals to momentum as return lag increases
- \blacktriangleright Our model \rightarrow differing noise trader horizons, overconfident informed, and uninformed
- Empirical evidence that supports the model
 - Reversals \$\propto around earnings annnouncements
 - \uparrow Momentum $\rightarrow \downarrow$ reversal (across countries and time)
 - ► Reversal profits ↑ in countries with ↑ uncertainty avoidance

Reversal profits ↑ in absolute retail imbalance
